ANTI-AIDS IMMUNOMODULATOR COMPLEX

The present invention relates to an anti-AIDS therapeutic vaccinal complex, which has vaccination effectiveness connected to the presence of non-specific antigens.

It is well known in bacteriology that the antigens
 5 at the surface of walls, membranes or capsules (combined or liberated in soluble form in culture medium) are of glycopro-
 teic, polypeptidic or polysaccharidic nature.

Recent vaccines have been widely publicized, associating with RNA (ribosomal origin) of such proteoglycanic
 10 or polysaccharidal membranal substances, extracts of pathogen-
 ic germs.

These vaccines use specific antigens corresponding to specifically predetermined microbial diseases.

However, the antigenic power is essentially connect-
 15 ed to the RNA level (of the ribosomes in particular) of the microbial cells, among others. The ICC (immunologically competent cells) use directly the RNA as active transporters.

To build our new vaccinal complex, instead of using a serotypical bacterial antigen, we have coupled (by prefera-
 20 bly covalent bonds) RNA (preferably of ribosomal origin) to a sequence of amino acids of glycoprotidic nature, present in collagen of type III (in humans, collagen represents approxi-
 mately one-third of the proteins of the organism; type III has been selected for its amino acid sequence and because it is
 25 present essentially in the skin and the vascular walls).

Moreover, RNA is already used in the preparation of acellular vaccines (cf. Infect. and Immunity, 1, 574-82, 1970). This RNA is stabilized by associative factors.

5 In our complex, we use as stabilizer cellular membrane fractions from the same germs as those which have served for the elaboration of ribosomal RNA. These membranal fractions contain all the peptidalglycanic substances and are known moreover as immunal adjuvants.

10 Contrary to convention, it is not necessary to have the same membranal fractions (glucopolysaccharidal or proteoglycanic) from the same microbial germs as those which serve to supply RNA by extraction of their ribosomes.

Constituents of the vaccinal complex according to the invention

15 A - Useful RNA of ribosomal origin can be extracted from the following strains, this list not being limiting:

- *Klebsiella pneumoniae*
- *Streptococcus* (pneumonia and pyogens)
- *Staphylococcus aureus*
- 20 - *Serratia marcescens*
- *Escherichia coli*
- *Salmonella typhimurium*
- *Corynebacterium* (*granulosum*, *parvum*, *acnes*)
- *Mycobacterium* (*tuberculosis*, *smegmatis*, *chelonei*)
- 25 - *Hemophilus influenzae*
- *Pneumococcus* type II

- *Rothia dento cariosus*
- *Bacterium coli*
- *Shigella dysenteriae*
- *Enterococcus*
- 5 - *Nocardia (asteroides, brasiliensis, rhodocrans, opaca, rubra)*
- *Bacillus* of Calmette and Guerin

The mean molecular weights of these RNAs are between 5.104 and 108 Daltons.

10 Many industrial processes exist for the preparation of RNA; there will be cited as example the process for the extraction of RNA described in Infect. and Immunity, 1, 574-82, 1970: the bacteria are agitated and then subjected to fractional precipitation, the ribosomal proteins are solubi-
15 lized, the precipitated RNA is treated with Pronase and finally, purified by ion exchange chromatography.

If RNA is obtained by enzymatic means, the final purification can be effected by molecular sieve chromatography. See particularly on this subject:

25 B - The membranal fractions of usable bacterial cells can be extracted from the following strains, the given list not being limitative:

1 - for capsular polysaccharides

- *Klebsiella pneumoniae*
- *Streptococcus pneumoniae*
- *Hemophilus influenzae*
- *Escherichia coli*

15 45).

C- Other adjuvant factors of immunity, in addition to
membranal fractions, are

- of collagen type III
- of sodium chloride

20 The Type III collagen used is characterized by:

a - amino acid sequences next to the following sequence
(the concentrations are expressed in g/kg):

	- aspartic acid	AA	51.5
	- hydroxyproline	HP	107.0
25	- threonine	TH	16.1
	- serine	SE	27.8
	- glutamic acid	GA	95.9

	- proline	PR	124.0
	- glycine	GL	149.0
	- alanine	AL	87.9
	- valine	VA	23.3
5	- methionine	ME	7.5
	- isoleucine	IL	14.4
	- leucine	LE	27.8
	- tyrosine	TY	6.7
	- phenylalanine	PA	14.4
10	- lysine	LY	28.6
	- histidine	HI	5.5
	- arginine	AR	73.0

b - analysis type as follows:

	- color	yellowish, white
15	- apparent density	250 g/l
	- humidity	6%
	- pH of a 10% solution	6.9
	- Engler viscosity at 40°C (17.75% solution)	2.5
20	- fatty material content	0.9%
	- ash content	2.2%
	- Fe + Cu + Ca content	462 mg/kg
	- heavy metals	not determinable by emission arc spectography
25	- elemental analysis	C 46.80%
		H 7.10%
		N 14.96%

The composition of the vaccinal complex according to the invention, associating RNA or ribosomal RNA fragments, membranal fractions (for example proteoglycanes of *Klebsiella pneumoniae*) and of type III collagen, completed by sodium chloride and an anti-inflammatory, permit, by administration of low doses giving rise to no toxicity, obtaining a high level of protection and of cure.

The preferred formulation is the injectable form of the composition described above, but it is possible to use other forms and/or other supports or additives compatible with medical usage.

Mechanism of the action of the vaccinal complex

The therapeutic vaccinal complex which has been described has the characteristics of a lymphokine which, adhering to the macrophages, inhibits the intra-cellular increase of the virus.

Since 1974-75 (A.S. and G.P. YOUNG), it has been considered that the inhibitory effect of the immune response to RNA was produced by different inhibitors.

This has lead us to conceive the vaccinal complex, according to the invention, which gives rise to the same inhibition of the replication of the HIV retrovirus.

YOUNG worked on a single bacterial strain (*Mycobacterium tuberculosis*), whose "parasitism" is solely intra-cellular.

VENNEMAN and colleagues believe, since 1972, that the true antigen could be associated with RNA, whose role would be that of an adjuvant. They vaccinated mice with ribosomal RNA, extracted with phenol at 65° from ribosomes of the strain *Salmonella typhimurium*. Thirty days after this vaccination, they noted that the animals are better protected than by live vaccinal strain (attenuated).

It is above all believed that the level of protection is a function of the quantity of RNA injected.

It is now known that ribosomal RNA extract of *Streptococcus pneumoniae* produces a protection of humoral nature and that ribosomal RNA extract of *Klebsiella pneumoniae* induces a natural cellular protection.

Preliminary experiments, by DUSSOURD d'HINTERLAND, FONTANGES and colleagues (Division of Microbiology of the Research Center of the Military Health Service of Lyon, France), have thus demonstrated that this mixture, injected in vivo in mice and guinea pigs, has an action on the alveolar macrophages.

This "transitory" effect occurs when dosing the phosphatase acid of the hemolyses regions directly in contact with the splenic cells of mice.-

Immunological studies carried out by DUSSORD d'HINTERLAND from ribosomal vaccines, induce in O.F. female mice the production of specific antibodies when they are administered to the animal in the presence of FREUND (incomplete) adjuvant or membranal protolycanes of *Klebsiella*.

The treatment with our vaccinal complex is as to itself followed by a cellular and humoral immunostimulant effect, with nonspecific action, but significant, on HIV. This action can be likened to the production of a "V.N.F." (Virus Necrosis Factor), because it is the organism of the patient himself which is urged to reject the infected cells (antigen P24 being, for this reason, reduced to zero in almost all cases).

The therapeutic technique of S. ROSENBERG is not identical to ours, although it is rather close. He localized on human DNA the gene which produces the "T.N.F." (Tumor Necrosis Factor). After having cloned on *Escherichia coli* and reproduced, he introduced it, with the aid of a vector virus, into lymphocytes T (Tueurs) which are found in tumors.

Our therapeutic mechanism permits producing a natural cloning thanks to the RNA (non-specific ribosomal bacteria) opsonized by the improved adjuvant (combination of membranal proteolycanes, of type III collagen, of sodium chloride).

This cloning induces a vaccination against idiotypes of the anti-HIV antibodies, as well as the production of antibodies against the site of bonding of the virus to the molecule CD4, in particular. To increase or inhibit the auto-immune anti-CD4 reaction (which contributes to lymphopeny CF4), it is necessary to use, during treatments with the vaccinal complex, corticoids (Betamethazone type) in the form

of disodium phosphate, at a dosage of 20 to 60 mg, by the IV or IM route.

5 This action is also accompanied by a production of endogenous interferon, as well as an activation of the N.K. cells.

The object of our immunomodulatory vaccinal complex is therefore to induce an immune response having for its effect to prevent or at least to reduce (to a possible auto defense threshold), the proliferation of an infectious agent, viral in this case, introduced into the organism.

Our therapeutic novelty consists among other things in moderating or suppressing the existence of "suppressive cellules" exerting a pro-infectious action.

15 Our treatment gives rise to an anti-AIDS reaction by a cellular and/or humoral defense response.

In conclusion, our therapeutic compound acts by directed evolution producing RNA molecules, which, binding to viral proteins, block the infection by AIDS retrovirus.

Techniques for administration of the vaccinal complex

20 The vaccinal complex can be administered by oral route, but the preferred method is by the parenteral route:

- * either by direct intravenous direction
- * or by slow perfusion
- * or again by subcutaneous injection.

25 This various techniques have been carried out experimentally with success.

The daily dosages and their frequency depend greatly on the condition of the patient. An overdose has no risk, given the very low toxicity of the complex.

By intravenous route, can be used frequencies of one week per month, each day of the week of treatment comprising a slow perfusion of 500 ml of a solution containing:

- 0.9% sodium chloride
- 40 µg of membranal saccharidic fractions (proteoglycanes of *Klebsiella pneumoniae*)

10 - 22 µg (ribosomal) RNA of:

- * *Diplococcus pneumoniae* 7 µg

- * *Streptococcus pyogens* (A 12) 7 µg

- * *Klebsiella pneumoniae* 7 µg

- * *Hemophilus influenzae* 1 µg

15 - 10 µg of type III collagen described above

- 8 mg of disodium phosphate of Betamethazone (namely 2 ml of injectable solution)

This treatment by slow IV perfusion can be followed by a treatment by subcutaneous injections of the patients which can be carried out on an ambulatory basis, each injection containing

- 40 µg of membranal saccharidic fractions (proteoglycanes of *Klebsiella pneumoniae*)

- 22 µg (ribosomal) RNA of:

25 * *Diplococcus pneumoniae* 7 µg

- * *Streptococcus pyogen* (A 12) 7 µg

- * *Klebsiella pneumoniae* 7 µg

* Hemophilus influenzae 1 µg

- 10 µg of type III collagen described above
 - 0.5 ml of 0.9% sodium chloride
 - 4 mg of disodium phosphate of Betamethazone (namely 1
- 5 ml of injectable solution).

This treatment can be performed for several months, until the seropositivity is completely negated (that is to say AgP24 = 0)

The following non-limiting examples are given to

10 illustrate the concrete results of our therapeutic vaccinal complex.

Example 1

Mr. J. A..., 65 years old, hemophilic, was infected during a transfusion received eight years previously. AIDS

15 and hepatitis (Group IV C2). A major deterioration took place in September, 1991. Hospitalized, he suffered from asthenia, loss of weight, intestinal troubles, rhino-sinusitis, etc... Treatment with AZT failed.

September, 1992 - beginning of treatment with our

20 vaccinal complex: series of IV perfusions, followed, in December, 1992, by a series of subcutaneous injections.

At present, there is observed:

- a good general condition
- weight gain
- 25 - seronegativity as to AgP24.

Example 2

Mme A. A..., 59 years old, wife of the preceding patient, underwent a serious deterioration in May, 1992 with asthenia and weight loss (Group IV A).

5 September, 1992 - beginning of treatment with our vaccinal complex: IV perfusion series, followed, in December, 1992, by a series of subcutaneous injections.

At present, there is noted:

- an excellent general condition
- 10 - regaining initial weight
- seronegativity as to AgP24

Example 3

Mr. E. C..., 30 years old, was contaminated by a sexual contact six years previously. AIDS was diagnosed in 15 1988 (Group IV C1). In 1992, the patient suffered asthenia, then the beginning of pneumocytosis (treatment with AZT + Bactrim Forte).

September, 1992 - beginning of treatment with our vaccinal complex: series of subcutaneous injections only, 20 with discontinuance of all other therapy.

At present, there is noted:

- an excellent general condition (having permitted an extension of professional activity)
- seronegativity as to AgP24;

25 These treatments by the vaccinal complex have been practiced on various patients at their express request and by

WO 94/22462

PCT/FR94/00184

reason of the obvious ineffectiveness of their previous treatments.

CLAIMS

1. Anti-AIDS immunomodulatory complex constituted by a mixture of selected bacterial anti-ribonucleic acids, of selected bacterial membranal fractions - glycopeptides and/or lipopolysaccharides - and of amino acids of type III collagen.

2. Immunomodulatory complex according to claim 1, characterized in that it comprises dual molecules constituted by the coupling of a functional amino acid arm ensuring bonding to a target, with an RNA genetic arm corresponding to the coded description of the composition of the functional arm.

3. Immunomodulatory complex according to claims 1 and 2, characterized by the production of antibodies directed against the site of linkage of the virus (on the CD4 molecule in particular) and the production of endogenous interferon.

4. Immunomodulatory complex according to claims 1 to 3, inducing, on seropositive patients, an anti-idiotypic vaccination against idiotypes of the anti-HIV antibodies, having for its effect negating the antigenemy P24.

5. Immunomodulatory complex according to one of claims 1 to 4, characterized by a formulation in a form such that it can be administered by different routes: perfusions, intravenous injections, subcutaneously, transdermal devices or the like, with the addition of sodium chloride.

6. Immunomodulatory complex according to one of claims 1 to 5, characterized by a formulation in such form that it permits simultaneous administration of major anti-

WO 94/22462

PCT/FR94/00184

inflammatories (corticoidal type), with immunosuppressive effects, to inhibit or diminish the anti-CD4 autoimmune reaction, which contributes to CD4 lymphopeny.
